ABSTRACT
A simple, selective, linear, precise and accurate RP-HPLC method was developed and validated for rapid assay of Silymarin in Bulk and Pharmaceutical tablet Formulation. Isocratic elution at a flow rate of 1ml/min was employed on symmetry Shimadzu LC-20 ATvp Kromasil C-18 column at ambient temperature. The mobile phase consisted of Methanol: Water: Acetonitrile (80:15:5 v/v). The UV detection wavelength was 285nm and 20μl sample was injected. The run time for Silymarin is 15min. The flow rate was found to be 1.5ml/min. The percentage recovery of the method was found to be 100.47%. The LOD and LOQ for Silymarin was found to be 10μg/ml and 40μg/ml respectively. The method was validated as per the ICH guidelines. The method was successfully applied for routine quality control analysis of pharmaceutical formulation. The HPLC method can be successfully applied for the routine quality control analysis of Silymarin formulations, which could be the better choices compared to the reported methods of literature

KEYWORDS: Silymarin, Rp- HPLC, UV detection, Recovery, Precise.

INTRODUCTION

IUPAC Name for Silymarin¹ is (2R,3R)-2[(2R,3R)-2-3-dihydro-3-(4-hydroxy-3-methoxyphenyl)-2-(hydroxymethyl)-1,4-benzo-dioxin-6-yl]-2-3-dihydro-3,5,7-trihydroxy-4H-1-benzopyran-4-one. Silymarin/silibinin provide an alternative treatment option for anti-cancer treatment.² Silibinin has also demonstrated anti-cancer effects against human prostate adenocarcinoma cells, estrogen-dependent and - independent human breast carcinoma cells, human ectocervical carcinoma cells, human colon cancer cells, and both small and nonsmall human lung carcinoma cells.³ There is also clinical evidence for the use of silibinin as a supportive element in alcoholic and grade Child ‘A’ liver cirrhosis.⁴ Silipide (trade name Siliphos), a complex of silymarin and phosphatidylcholine (lecithin), is about ten times more bioavailable than silymarin.⁵ Tian-ming Ding, etal⁶, Determined by RP-HPLC consisted of column: Shim-pack VP-ODS (150×4.6mm i.d. 5µm) and Pre-column (10×4.6 mm i.d. 5µm); mobile phase: methanol and solvent mixture (water: DIOXANE=9:1) by gradient; flow rate: 1.5ml/min; column temp.: 40°C; detector wavelength: 288nm; The recovery of 99.66% for silychristin, 99.48% for silydianin, 100.0% for silybin and 98.72% for isolsilybin. F. M. Hammouda etal⁷. An HPLC assay for the determination of silymarin in the fruits of Silybum marianum is given. T. radjabian, etal⁸, aim of this research was to study the variations in composition and content of flavonolignans of silymarin samples from seeds of some native milk thistle ecotypes of Iran, along with a foreign cultivar. Silymarin was extracted by a two-step (defatting and extraction) process using n-hexane, ethyl acetate and methanol in a Soxhlet extraction from the seeds. A.V.D. Nagendra kumar et.al.,⁹ proposed the expected separation and peak shapes were obtained on chromosil C18 (250mm x 4.6mm, 5µm) column. A mixture of methanol: 0.1% orthophosphoric acid: acetonitrile in the ratio of 80:05:15/v/v/v was proved to be the most suitable of all the combinations since the chromatographic peak obtained was better defined and resolved and was almost free from tailing. The flow rate was 1.5ml/min and effluents were monitored at 256nm. The Rt for telmisartan was 2.7min. Recovery of telmisartan from tablet formulation was found to be 99.41%. A.V.D.
Nagendra kumar et al. [10] proposed a New Validated HPLC Method for the Estimation of Oxazepam In Pharmaceutical Formulation. Isocratic elution at a flow rate of 1.0ml/min was employed. The chromatographic analysis was performed on a ODS 5µm (4.6mm x 15cm) or equivalent column at ambient temperature. The mobile phase consisted of Methanol: Water in the ratio of 65:35v/v. The UV detection wavelength was 230nm and 100µl sample was injected. Flow rate was found to be 1.0. The retention time for Oxazepam was identified. The Average percentage recovery of the method was in the range of 0.5.

EXPERIMENTAL

2.1 Instrumentation
Peak HPLC containing LC 20AT pump and variable wavelength programmable \textit{PDA detector} and Rheodyne injector was employed for investigation. The chromatographic analysis was performed on a Kromasil C_{18} column 250 x 4.6mm ID with 5µ particle size and the column were maintained at ambient temperature. Degassing of the mobile phase was done using a Loba ultrasonic bath sonicator. A Denwar analytical balance was used for weighing the materials.

2.2 Chemicals and solvents
The reference sample of levalon was obtained from Cipla, Mumbai. The Formulation was procured from the local market. Water, Methanol and Acetonitrile used were of HPLC grade and purchased from the chemicals procured from E-Merck, India, Limited.

2.3 The mobile phase
The mobile phase was prepared by mixing Methanol: Water: Acetonitrile (80:15:5 v/v). Prepared mobile phase was filtered through 0.45µ membrane filter and sonicated. Sample solution was prepared by dissolving the drug in mobile phase and sonicated for 30 minutes.

2.4 Preparation of solutions
2.41 Preparation of mobile phase solution
The mobile phase was prepared by mixing Methanol and Water: Acetonitrile (80:15:5 v/v) by ultra bath sonicator for 30min.

2.42 Preparation of standard solution
Stock solution of Silymarin was prepared by dissolving accurately weighed 5mg of drugs in 10ml Methanol. The prepared stock solutions were stored away from light. From the stock, standard solutions was freshly prepared during the day of analysis.

2.43 Preparation of working standard solution (A.P.I)
From the stock solution 20µg/ml solution was prepared.

2.44 Preparation of working standards for linearity
Solutions in the concentration range of 0.5-2.5µg/ml were prepared from the standard working solution.

2.45 Preparation of formulation sample solution
10mg of formulation powder was taken from LEVALON (70 mg formulation) and dissolved in 10ml of mobile phase and injected into HPLC and chromatogram was recorded. The amount of drug present in the 1mg formulation was calculated from linearity graph.

3. Method Development
For developing the method, a systematic study of the effect of various factors was undertaken by varying one parameter at a time and keeping all other conditions constant. Method development consists of selecting the appropriate wave length and choosing stationary and mobile phases. The following studies were conducted for this purpose:

3.1 Detection of wavelength
The spectrum of 10ppm solution of Silymarin was recorded separately on UV spectrophotometer. The peak of maximum absorbance wavelength 285nm was observed.

3.2 Choice of stationary phase and mobile phase
Finally the expected separation and peak shapes were obtained on Kromasil C_{18} column 250 x 4.6mm ID with 5µ particle size.

3.3 Flow rate
Flow rates of the mobile phase were changed from 1.0-2.0ml/min for optimum separation. It was found from experiments that 1.5ml/min flow rate was ideal for elution of analyte.

4. Validation Procedure and Requirements
The analytical performance of the method of analysis was checked for specificity, System suitability, detection limit, and method precision.

4.1 Linearity and Calibration
Linearity was assessed by performing single measurement at several analyte concentration varying quantities of stock standard solution diluted with the mobile phase to give a concentration of 0.5,1.0,1.5,2.0,2.5µg/ml Injection was made at intervals of 10min. The linearity was tested for the concentration ranging from 0.5µg/ml to 2.5µg/ml. The peak area ratio of the drug was plotted against concentration. The linearity was evaluated by linear regression analysis, which was calculated by the least square regression method.

4.2 Precision
Reproducibility was performed by injecting three replicates concentrations of standard and sample solutions which were prepared and analyzed by same analyst on same day. Inter-day variations in the peak area of drug solutions and the amount of drug were calculated in terms of Percentage Relative Standard Deviation. The sample concentration is 20µg/ml.
4.3 Accuracy
Recovery assessment was obtained by using standard addition technique which was by adding known quantities of pure standards at three different levels in 80%, 100% and 120% to the pre analysed sample formulation.

4.4 ASSAY
The estimation of drug in pharmaceutical dosage forms. LEVALON 70mg strength was evaluated for the amount of Silymarin present in the formulation. Each sample was analyzed in triplicate after extracting the drug. The amount of drug present in formulation was calculated by comparing the mean peak area from standard.

4.5 Intermediate Precision or Ruggedness
Inter-day variations were performed by using six replicate injections of standard and sample solutions of concentrations which were prepared and analyzed by different analyst on three different days over a period of one week. Ruggedness also expressed in terms of percentage relative standard deviation.

4.6 Robustness
Robustness was carried out by varying two parameters from the optimized chromatographic conditions.

4.7 Specificity
The method was determined as specific by comparing test results obtained from analyses of sample solution containing excuse ingredients with that of test results those obtained from standard drug.

4.8 System Suitability Parameter
System suitability tests were carried out on freshly prepared standard stock solutions of Silymarin and it was calculated by determining the standard deviation of Silymarin standards by injecting standards in five replicates at 6 minutes interval and the values were recorded.

5. Silymarin Analysis In Serum
From a local hospital blood was collected and serum was separated. 10ml of this serum was taken in a test tube and added 100µl of diltizem hydrochloride (1µg/ml) and 0.1ml of 1M NaOH and 5ml of dichloromethane and mixed about 20min in vortex mixer and centrifuged at 3000rpm for 10min. From this centrifuged solution 4ml of organic layer was separated and evaporated to dryness to get residue. To this residue 100µl of 1M acetic acid and 3ml of n-Hexane and mixed for 5min by vortex mixer and evaporated the organic layer and finally the remaining sample was injected into HPLC and chromatogram was recorded. The amount of drug present in the blood sample was calculated from linearity graph.

5.1 Serum Data of Silymarin
Drug estimation in human serum by developed protocol. From linearity graph we can estimate amount of drug present in the sample. Amount of Silymarin present in serum is 9.24µg/10ml.

6. RESULT AND DISCUSSION
The Reverse Phase High Performance Liquid Chromatography method was developed a stability indicating assay method. Pure drugs chromatogram was run in different mobile phases containing methanol, acetonitrile, THF, and different buffers like potassium dihydrogen phosphate, sodium dihydrogen phosphate, Ortho phosphoric acid in different volumes ratios. Different columns like C₈, C₁₈, phenyl, cyano with different dimensions were used. Then retention time and tailing factor were calculated. Finally Methanol and Water and Acetonitrile in the volume of ratio 80:15:5 v/v (P:// 5.0) and Kromosil C₁₈ analytical column was selected which gave a sharp and symmetrical peak with 1.76 tailing. Calibration graph was found to be linear at range 0.5µg/ml to 2.5µg/ml. five different concentrations of Silymarin in range given above were prepared and 20µl of each concentration injected in HPLC as sown in the Figure no: 2. The slope (m) and intercept (c) obtained were found to be 94780.08 and -0.087404319. The correlation of coefficient (r²) obtained was found to be 0.9992 as shown in the Table no: 2. It was observed that the concentration range showed a good relationship. The limit of detection for Silymarin was found to be 10µg/ml and the limit of quantification was found to be 40µg/ml. It proves the sensitivity of the method. The Percentage assay of Silymarin in formulation was found to be 100.47%. as shown in the Table no: 1 and figure no: 4. The relative standard deviation value obtained was below 1 which indicates the precession of the method. The validation of the proposed method was further verified by recovery studies. The data was presented by in the Table no: 2 and figure no: 3. The percentage recovery was found to be 99.76% which shows a good index of accuracy of the developed method. The amount of drug present in the human serum sample was calculated from the linearity graph was found to be 9.24mg/10ml as shown in Figure no: 5.

6. CONCLUSION
The RP-high performance liquid chromatographic method developed and validated for the analysis of Silymarin and for the serum studies from their formulations was found to be accurate and precise. This method is more useful than the reported methods of analysis in the literature. Thus, the proposed HPLC method can be successfully applied for the routine quality control analysis of Silymarin formulations.
